Introduction and Method

The Catalan Research Institute for the Governance of the Sea (ICATMAR) has developed, in the framework of the 2030 Maritime Strategy of Catalonia, a monitoring program in collaboration with the commercial bottom trawling fleet to characterize all fractions of the catch, including marine litter. Data collection began in 2018 and will continue to offer the data needed to sustain fisheries and improve management plans. This report presents the data collected and analyzed throughout the year 2023 as an overview of the marine litter fraction of the catch passively caught by bottom trawlers in the Catalan coast, considered a Fishing for Litter strategy.

Data on catch composition for the bottom trawl fishery are shown by port for each of the nine ports sampled. The object of study is macro-benthic marine litter, in other words, the debris big enough to be caught by the bottom trawling which is accumulated on the seafloor. The Catalan coast was divided in three zones, with a total of 9 base ports sampled, from north to south: Roses, Palamós, Blanes, Arenys de Mar, Barcelona, Vilanova i la Geltrú, Tarragona, L'Ametlla de Mar and La Ràpita (Figure 1). Each zone was sampled monthly with a quarterly frequency per port.

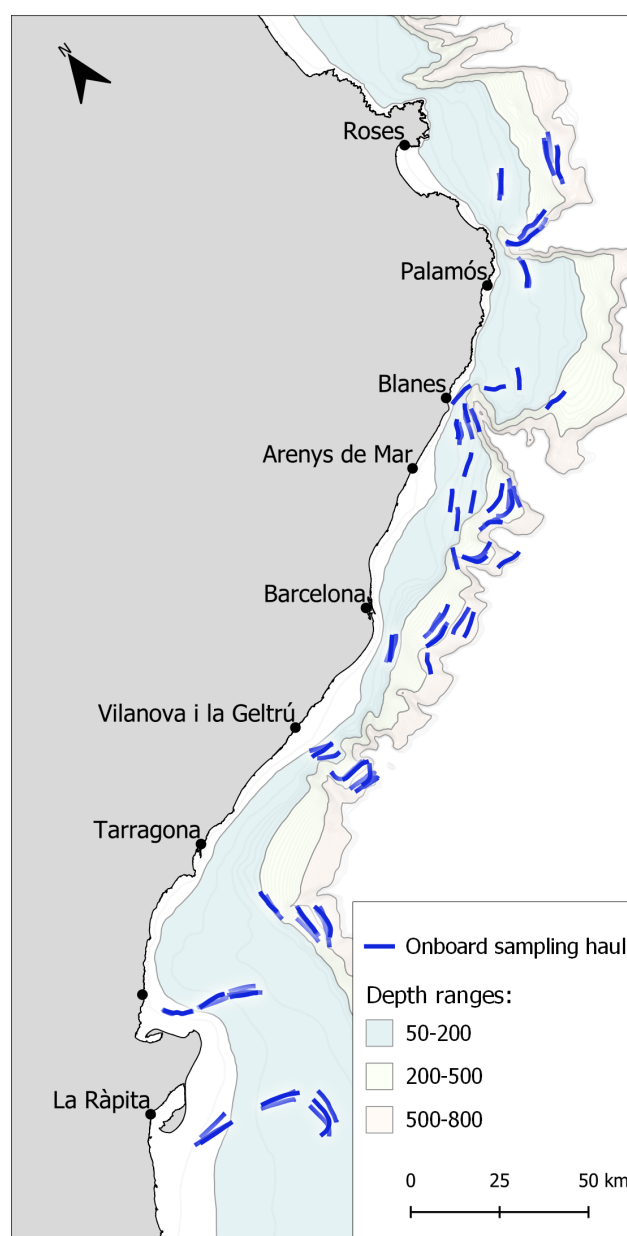

Figure 1. Study area and main fishing ports of ICATMAR bottom trawl fisheries monitoring program in the Northern GSA 6.

In the north and center zones, the sampling depth ranges defined are deep shelf (75 – 200 m), upper slope (200 – 500 m), and lower slope (500 – 800 m). In the southern area, which has a distinct geomorphological structure and bottom sedimentary characteristics, the defined sampling depths are coastal delta

shelf (< 40 m), middle delta shelf (40 – 75 m), and deep shelf (75 – 200 m). Each sampling haul was GPS-recorded with a start and end point, fishing time and gear width. These measurements allowed the calculation of the fishing area to standardize marine litter catches for comparison. The total catch, or a fraction in the case of a very abundant catch, was taken to the ICM-CSIC laboratory to classify and weigh (wet) all marine litter caught in the nets, as described in Table 1. Details on methodology can be found in ICATMAR 24-05.

Table 1. Classification of the marine litter categories in the laboratory, following Balcells et al. (2023).

Category	Description
Metal	Items or pieces made with ferrous and non-ferrous metals, i.e. cans, lids
Plastic	Items or pieces made with plastic, i.e. bags, containers
Rubber	Items or pieces made with rubber, i.e. balloons, boots, tyres
Textiles	Clothes and pieces of fabric
Wood	Items and pieces made with wood, i.e. corks, boxes or poles
Other waste	All other marine litter which does not fit in the specific categories, including clinker, the residue from coal-burning steamships

2

Marine litter from the bottom trawl fishery in Catalonia

In 2023, a total of 105 bottom trawl sampling hauls were conducted. Of the total catch, 3% was natural debris mass and 1% was marine litter.

The average marine litter mass was 2% for the period 2019-2022 and 1% for 2023 (Figure 2). For marine litter, i.e. anthropogenic waste, the categories with the highest proportions were plastic in both periods compared (Figure 3).

Figure 2. Catch composition in Catalonia. Percentage by weight of landings, discarded, natural debris and marine litter.

Figure 3. Categories of marine litter with higher mass including all hauls in each year.

Regarding the different depths, the composition of marine litter was found in all fishing grounds, representing a similar fraction within the whole catch (Figure 4).

Figure 4. Catch composition for Catalonia. Percentage by weight of landings, discarded, natural debris and marine litter fraction in each métier including all hauls in each period.

Figure 5: Categories of marine litter with higher mass. Percentage in weight including all hauls within each period and métier.

The composition of marine litter at different depths was variable but plastic was the category that accounted for the highest proportion globally. This proportion was similar through time, with an average of 20.32 kg/km² in the period 2019-2022 and 17.33 kg/km² in 2023 (Table 2, Figure 5). The second most common category was other waste, in all studied periods. This category includes clinker, which is the residue of burned coal from steamships (Galimany et al. 2019). This item is heavy and thus, since the data is presented in mass units, it represents a considerable fraction of waste despite this item is not generated anymore as there no steam ships navigating the Mediterranean Sea. Rubber was the category with the lowest proportion, both in global average but also at all depths.

Marine litter composition by port

This section contains information on the composition in weight of the marine litter fraction of the catch by port, for the 9 ports sampled. Each port recorded different amounts of marine litter being Barcelona the port with the highest global amount, i.e., 43.54 kg/km² in the period 2019-2022 and 17.74 kg/km² in 2023 (Table 3). The port with the lowest amount was l'Ametlla de Mar with 0.58 kg/km² in the period 2019-2022 and 2.06 kg/km² in 2023 (Table 3).

4

Conclusions

Marine litter is a global problem, also found along the Catalan coast, at all studied depths. Fishing for Litter strategies can provide useful information and help identify the type and location of the marine litter accidentally caught by bottom trawlers. Using this strategy, the main findings include:

- Marine litter represent the lowest fraction of the catch for bottom trawlers in the Catalan continental shelf, both historically and at present time;
- Both, coastal and deeper shelf métiers, accumulate the largest amount of marine litter from fishing grounds;
- The category Plastic, even if they are items made of out a very light material, represents the greatest proportion of the marine litter fraction, with an average of 20.32 kg/km². In contrast, Rubber is the least frequent fraction, with only 0.30 kg/km² in average;
- When analyzed by port, the amount and type of marine litter varies along the coast. The greatest amounts, though, were observed in the central area of Catalonia, with the plastic fraction dominating the marine litter. The southern area is the only area where Wood is abundant.
